Holographic study of Wilson loop in the anisotropic background with confinement/deconfinement phase transition

Slepov Pavel

Moscow State University

Valday, 29.05.2018
Motivation

**Purpose:** Study of the QCD phase diagram as a function of temperature $T$ and chemical potential $\mu$ in the anisotropic background.

Holographic methods for calculating of the loops (J. Maldacena, D. Gross and others).

Holographic approach to the study of QGP is actively developed. O. Andreev and V. I. Zakharov, [hep-ph/0604204]
Formulation of the problem

It is natural to expect, that the phase transition depends on the orientation of the quark pair relative to the anisotropy axis.

Anisotropy axis in the QGP created in the HIC is defined by the axes of ions collisions. Confinement/deconfinement phase transition line depends on the angle $\theta$ between quarks’ line and heavy ions collisions line.
Background

\[ ds^2 = G_{\mu\nu} dx^\mu dx^\nu = \frac{b(z)}{z^2} \left[ -g(z) dt^2 + dx^2 + z^{2 - \frac{2}{\nu}} (dy_1^2 + dy_2^2) + \frac{dz^2}{g(z)} \right], \]

\( \nu \) – anisotropic parameter, \( b(z) = e^{cz^2} \) – warp factor, \( z_h \) – horizon, AdS radius \( L = 1 \), blackening function \( g(z) \):

\[
g(z) = 1 - \frac{z^{2 + \frac{2}{\nu}}}{z_h^{2 + \frac{2}{\nu}}} \frac{\mathcal{G}\left(\frac{3}{4} cz^2\right)}{\mathcal{G}\left(\frac{3}{4} cz_h^2\right)} - \frac{\mu^2 cz^{2 + \frac{2}{\nu}} e^{\frac{cz^2}{2}}}{4 \left(1 - e^{\frac{cz^2}{4}}\right)^2} \mathcal{G}(cz^2) +
\]

\[
+ \frac{\mu^2 cz^{2 + \frac{2}{\nu}} e^{\frac{cz_h^2}{2}}}{4 \left(1 - e^{\frac{cz_h^2}{4}}\right)^2} \frac{\mathcal{G}\left(\frac{3}{4} cz^2\right)}{\mathcal{G}\left(\frac{3}{4} cz_h^2\right)} \mathcal{G}(cz_h^2), \quad \mathcal{G}(x) \equiv \sum_{n=0}^{\infty} \frac{(-1)^n x^n}{n!(1 + n + \frac{1}{\nu})}
\]

I.Ya.Aref'eva, K.Rannu and P.Slepov (in preparation)
Expectation value of the temporal Wilson loop: $W[C_\vartheta] = e^{-S_{\vartheta,t}}$.

Orientation along vector $\vec{n}$: $n_x = \cos \vartheta$, $n_y = \sin \vartheta$.

World sheet parametrization:

\[
\begin{align*}
X^0 & \equiv t = \xi^0, \\
X^1 & \equiv x = \xi^1 \cos \vartheta, \\
X^2 & \equiv y_1 = \xi^1 \sin \vartheta, \\
X^3 & \equiv y_2 = \text{const}, \\
X^4 & \equiv z = z(\xi^1).
\end{align*}
\]
Nambu-Goto action

Components of the induced metric: $h_{\alpha\beta} = G_{\mu\nu} \partial_\alpha X^\mu \partial_\beta X^\nu$

Lagrangian: $\mathcal{L} = \sqrt{-\det h_{\alpha\beta}}$

Born-Infeld-type action:

$$S = -\frac{\tau}{2\pi\alpha'} \int d\xi^1\ M(z) \sqrt{\mathcal{F}(z, \theta) + z'^2},$$

$$\tau = \int d\xi^0, \quad z = z(\xi^1)$$

$$M(z) = \frac{b(z)}{z^2}$$

$$\mathcal{F}(z, \theta) = g(z) \left(z^2 - \frac{2}{\nu} \sin^2(\theta) + \cos^2(\theta)\right)$$

Effective potential:

$$\mathcal{V}(z) \equiv M(z) \sqrt{\mathcal{F}(z, \theta)}$$
First integral

First integral of motion:

\[ \mathcal{I} = \frac{M(z) \mathcal{F}(z, \theta)}{\sqrt{\mathcal{F}(z, \theta) + z'^2}} \]

First integral can be expressed as:

\[ \mathcal{I} = M(z_{\text{min}}) \sqrt{\mathcal{F}(z_{\text{min}}, \theta)}, \]

\( z_{\text{min}} \) - point at which \( z'(\xi) = 0 \) and \( \mathcal{V}'(z_{\text{min}}) = 0 \)

Character length of string:

\[ \ell = \int_{0}^{z_{\text{min}}} \frac{2}{\sqrt{\mathcal{F}(z, \theta)}} \sqrt{\left( \frac{\mathcal{V}(z)}{\mathcal{V}(z_{\text{min}})} \right)^2 - 1} \, dz \]

\( \mathcal{V}(z) \equiv M(z) \sqrt{\mathcal{F}(z, \theta)} \)
Conditions of the phase transition

We study the character length behaviour at special points ⇒

expansion of $V^2(z)/V^2(z_{\text{min}})$ in the Taylor series at the point $z_{\text{min}}$:

$$\frac{V^2(z)}{V^2(z_{\text{min}})} = 1 + V_1 \cdot (z - z_{\text{min}}) + V_2 \cdot (z - z_{\text{min}})^2 + o((z - z_{\text{min}})^2)$$

$$V_1 \equiv \frac{2V'(z_{\text{min}})}{V(z_{\text{min}})}$$

$$V_2 \equiv \frac{V''(z_{\text{min}})}{V(z_{\text{min}})} + \frac{V'(z_{\text{min}})^2}{V^2(z_{\text{min}})}$$

$\downarrow$

$$\ell = 2 \int_{0}^{z_{\text{min}}} \frac{dz}{\sqrt{F(z, \theta)(V_1 \cdot (z - z_{\text{min}}) + V_2 \cdot (z - z_{\text{min}})^2)}}$$

For the confinement/deconfinement phase transition the character length $\ell$ must be infinite for $z \to z_{\text{min}}$ $\Rightarrow$ two different cases: $V'(z) = 0$ and $V'(z) \neq 0$. 
Conditions of the phase transition

1) $V'(z) \neq 0 \implies$ we can consider the first order only:

$$\ell = 2 \int_0^{z_{min}} \frac{dz}{\sqrt{F(z, \theta)V_1(z - z_{min})}} \sim \sqrt{\frac{z - z_{min}}{F(z_{min}, \theta)V_1}}$$

$\implies \ell \to 0$ as $z \to z_{min} - 0$

2) $V'(z) = 0 \implies$ we have to use the second order:

$$\ell = 2 \int_0^{z_{min}} \frac{dz}{\sqrt{F(z, \theta)V_2 \cdot (z_{min} - z)}} \sim \sqrt{\frac{V}{V''(z_{min})F(z_{min}, \theta)}} \log(z_{min} - z)$$

$\implies \ell \to \infty$ as $z \to z_{min} - 0$

Potential with the dilaton field:

$$V_\theta(z) = \frac{b(z)e^{\sqrt{\frac{2}{3}}\phi(z)}}{z^2} \sqrt{g(z) \left(z^2 - \frac{2}{\nu} \sin^2(\theta) + \cos^2(\theta)\right)}$$
Conditions of the phase transition

So we solve the equation $V'(z) = 0$:

$$DW_\theta \equiv cz + \frac{1}{\nu z} \sqrt{\frac{2}{3}} \sqrt{3c \nu^2 z^2 \left( \frac{cz^2}{2} - 3 \right) + 4\nu - 4 + \frac{g'}{2g} - \frac{2}{z} + \frac{(1 - \frac{1}{\nu}) z^{1-\frac{2}{\nu}} \sin^2(\theta)}{\cos^2(\theta) + z^{2-\frac{2}{\nu}} \sin^2(\theta)} \bigg|_{z=z_{DW\theta}} = 0$$

This expression leads to the particular cases $\theta = 0^0, 90^0$:

$$DW_x \equiv cz + \frac{1}{\nu z} \sqrt{\frac{2}{3}} \sqrt{3c \nu^2 z^2 \left( \frac{cz^2}{2} - 3 \right) + 4\nu - 4 + \frac{g'}{2g} - \frac{2}{z} \bigg|_{z=z_{DWx}} = 0,$$

$$DW_y \equiv cz + \frac{1}{\nu z} \sqrt{\frac{2}{3}} \sqrt{3c \nu^2 z^2 \left( \frac{cz^2}{2} - 3 \right) + 4\nu - 4 + \frac{g'}{2g} - \frac{\nu + 1}{\nu z} \bigg|_{z=z_{DWy}} = 0.$$
Phase diagram

\[ T(z_h, \mu, c, \nu) = \frac{g'(z_h)}{4\pi} = \frac{e^{-\frac{3cz_h^2}{4}}}{2\pi z_h} \left| \frac{1}{\mathcal{G}\left(\frac{3}{4} cz_h^2\right)} + \frac{\mu^2 cz_h^2 + \frac{2}{\nu} e^{\frac{cz_h^2}{4}}}{4 \left(1 - e^{\frac{cz_h^2}{4}}\right)^2} \right| \left(1 - e^{\frac{cz_h^2}{4}} \frac{\mathcal{G}(cz_h^2)}{\mathcal{G}\left(\frac{3}{4} cz_h^2\right)}\right) \]

Figure 1. A. The trace anomaly, energy density and pressure for two flavors of twisted mass Wilson fermions at \( m_\pi = 360 \text{ MeV} \). The plot from \([10]\). B. The QCD phase diagram supposes to study a complicated real time phenomena – thermalization. We also do not know much from experiments about the details of the QGP formation in HIC, one can just estimates the time of QGP formation as well as the total multiplicity (there are arguments that the main part of particles is produced during the QGP formation) \([13, 14]\). The QGP formation has been the subject of the active studies within holographic approach in last years (see \([15–17]\) and there in). Initially this problem was considered in AdS background \([18–24]\) and total multiplicity within this approach was estimated as \( M_{\text{AdS}} \ll s_0^{\frac{33}{3}} \), \( (1.1) \). For the improved holographic background the estimation was \( M_{\text{IHQCD}} \ll s_0^{\frac{22}{22}} (1 + \log \text{corrections}) \), \( (1.2) \). The experimental multiplicity dependence on energy \( [13, 14] \) is \( M_{\text{LHC}} \ll s_0^{\frac{1.155(4)}{1.155(4)}} \), \( (1.3) \), and it has been shown in \([26]\) that this dependence \( (1.3) \) requires a non-stable background. In \([27]\) it has been shown that the model that reproduces the Cornell potential also gives a correct energy dependence of multiplicities if we assume that the multiplicity is related with the dual entropy produced during a limited time period. However in this consideration there is a limitation on the possible energy of colliding shock walls \([27]\). Since in this consideration we have used a more or less general isotropic background reproducing AdS at UV and confinement at IR, we can think that the assumption about the isotropic background prevents to reproduce \( (1.3) \) at high energy.
Angles $\theta = 10^0$ (brown), $\theta_{cr1} = 22^0$ (green)
Angles $\theta = 45^0$ (red), $\theta_{cr2} = 54^0$ (cyan)
Angles $\theta = 60^0$ (orange), $\theta_{cr3} = 78^0$ (pink)
1) The dependence of the confinement/deconfinement phase transition on the orientation of the timelike Wilson loop is studied.

2) The expansions for the arbitrary angle are generalized.

3) The critical angles values ($\theta_{cr1} = 22^0$, $\theta_{cr2} = 54^0$, $\theta_{cr3} = 78^0$) are obtained. At $\theta_{cr2} = 54^0$, the Hawking-Page phase transition of the background metric coincides with the confinement/deconfinement phase transition. For angles $\theta < \theta_{cr2}$ the first order phase transition takes place at the top of the phase diagram.

Thank you for your attention!
